ID: 11834312

So how I set up my programming assignment is that the way I started off the assignment was to do 3 structs I did one for the cacheline and one for the cachset, and cache. The first function I created for the project is called the init cache. And the whole point of this function is that it helps set up and memorize the cache data memory before you start any trace operations. That is the whole point of the Cache * init. Now the other function that I distributed is called void free_cache(Cache* cache) the whole point of this function is to clean up all the memory was in the previous function so that is what the whole point of this function is to help clean up the memory from the previous function. Now the next function that I created is by far the most important function of this programming assignment. It is the heart of the simulator. This is the function in which checks for hits, misses, eviction. That is why this function is very important because it checks the hits and misses and eviction that were made in the entire program. The next function after that is the process_op this function is in charge of the Makefile function that I did in this program. The whole point of the print_usage function is to help make sure to help run the simulator for the entire program. Now the last function is print_summary all this function does is that it tracks down the statistics of how many times your cache was able to hit miss or eviction that is the whole point of the print_summary.
